

**DEVELOPMENT AND EVALUATION BASED ON NATURAL
LANGUAGE PROCESSING MODEL FOR SENTIMENT
EXPRESSED
ON BRAND AND PRODUCTS EMOTIONS**

PROJECT OVERVIEW

Overview

This project develops and evaluates a Natural Language Processing (NLP) model to analyze sentiment expressed in Twitter conversations about technology brands and products, with a primary focus on Apple and Google.

Data

9,093 crowd-sourced, human-labeled tweets from 2013 (CrowdFlower).
Three columns: tweet text, brand target, and sentiment label.

Outcome

A trained & interpretable SVM classifier that identifies Positive, Negative, and Neutral sentiment with actionable insights.

BUSINESS PROBLEM

Organizations rely on social media data to understand customer experiences and brand perception, but the large volume of online conversations makes manual analysis difficult

OBJECTIVES

01

Determine the extent to which
tweet content reflects sentiment

02

Assess the distribution of sentiment
across tweets based on brands
mentioned

03

Analyze the distribution of target
subcategories represented within
tweet content

04

Examine the influence of tweet
content and sentiment on target
categories

05

Analyze customer complaints
expressed toward specific brand
products

Duplicate Detection

Brand Name Standardization

Product Category Consolidation

Missing Target Handling

Label Normalization

VISUALIZATION

The extent to which tweet content reflects sentiment

Distribution of sentiment across tweets based on the brands mentioned within the tweet text

Distribution of target subcategories represented within tweet content

Influence of tweet content and sentiment on target categories

Customer complaints expressed in tweets toward specific brand products

APPLE vs. GOOGLE: MAIN CUSTOMER COMPLAINTS

INSIGHT

- The dominant takeaway is that 59.3% of the entire dataset (5,371 tweets) is categorized as Neutral.
- For both companies, the majority of the conversation is Neutral. Google leans more heavily into neutrality at 63.8%., Apple sits at 51.4%. Apple Negative Sentiment: 7.8%, Google Negative Sentiment: 5.4%

INSIGHT Cont...

- The most striking feature of the dataset is the dominance of the "No specific brand" category,

At 5,784 tweets, it accounts for 63.8% of the entire dataset

- Positive sentiment is the primary driver for both brands, making up 80.6% of the Apple-labeled segment and 81.7% of the Google-labeled segment.

INSIGHT Cont..

- Negative sentiment is the secondary driver, accounting for 16.3% of Apple labels and 15.0% of Google labels.
- App crashes is Apple's biggest individual complaint (21.4%), while Android bugs (23.5%) and Slow updates (19.8%) dominate over 43% of the entire negative conversation chart

MODEL INTERPRETABILITY

LOCAL INTERPRETABILITY (LIME)

Individual tweet explanations

Customer sentiment correlates most strongly with specific product mentions — not brand in general.

iPhone

iPad

Android

Google

Apple

GLOBAL INTERPRETABILITY

What the model learned overall

iPad

Weight: 2.74 • POSITIVE

Link

Weight: 5.38 •
EVENT/CONTEXT

Apple

Weight: 1.99 • POSITIVE

App

Weight: 0.79 • POSITIVE

Nothing

Weight: 0.47 •
NEGATIVE

Didn't

Weight: 0.36 •
NEGATIVE

LIMITATIONS

Small, Dated Dataset

- The dataset is relatively small (9,093 tweets)

Twitter-Only Coverage

- Dataset does not represent sentiments from other platforms

Sarcasm & Irony

The dataset originates from 2013, may not reflect current social media trends

Informal Language

- Difficult to interpret sarcasm, irony, humor, and context-dependent expressions

Class Imbalance

- Informal language, abbreviations, emojis, and slang can reduce classification accuracy

CONCLUSION AND RECOMMENDATION

Conclusions

- ✓ Neutral sentiment remained challenging to distinguish
- ✓ Most social media discussions are neutral, while positive substantially outweighs negative sentiment across major brands.
- ✓ Customer complaints identified provide insights for product improvement and customer experience management

Recommendations

- 1 Deploy the model as a real-time sentiment to resolve customer complaints promptly
- 2 Expand the dataset with more recent social media data
- 3 Improve minority-class detection using advanced imbalance handling techniques
- 4 Continuously retrain models to adapt to evolving language patterns

NEXT STEP

- Apply resampling techniques for imbalance
- Improve feature engineering.
- Conduct deeper error analysis.

Thank You
